W. MATTHEWS.

Rice Cleaning.

Patented Aug. 27, 1835.

Aug 27 1835

William Mathews of Charleston South Carolina
Letters Patent

The Schedule referred to in these Letters Patent and making part of the same containing a description in the words of the said William Mathews himself of the improvement in the machine for threshing Rice or any other small grain

To all whom these presents shall come.. Be it known that I William Mathews of Charleston in the District of Charleston and State of South Carolina have invented a new and useful improvement in the machine for threshing Rice or any other small grain and that the following is a full and exact description of the construction and operation of the said machine as invented or improved by me. The method of construction will be best understood by reference to the annexed drawings, in which the letter A represents the frame which is of an oblong shape and enclosed. A¹ The top piece of this frame upon which is supported a beating cylinder B. which may be made either with stationary beaters having pins to teeth along the outer edge of each Row of an oblong shape say about half an inch by three quarters, or the beaters may be of that kind called hinge beaters which have already been used and are moveable upon a bar passing from head to head of said cylinder and forming partial revolving theron, pins or teeth being used on the outer edges. The letter C represents these beaters. D. is the bed of these beaters and forms the concave in which they revolve. The surface of this bed is cut into angular projections E. fortified by the application of a strip of sheet iron along the angles.

These angles are opposed to the direction of the revolution of the beaters. F is a small pulley of about one inch and a half ⁱⁿ diam. on the end of the axis of the beating cylinder. on the other end is a small spur wheel of eight teeth or cogs at G. and this is the driving end, and instead of a pulley which is apt to slip. and does not give a sufficiently steady and continuing motion. I use a small prop shaft H let on to the said axis by a square hole into a cross. which shaft is applied the fixture from the driving power. The cog wheel G works into a larger one I. of twenty nine teeth which is fastened on to the end of the fusing Roller J. which revolves between the upright bars K which are connected at the bottom and run forward in front of the fusing

roller as is shown in fig 1. where there is a cut groove L, in the said projection for the purpose of adjusting the other pair of upright connected bars M in which the roller of the feeding table N, named the feeding rollers turns, a groove being also cut therein so that by loosening the screw O the rollers N, may be set nearer to the feeding rollers at pleasure. I have tried I prefer of keeping this feeding roller in down to the proper pressure is by means of the lever and weight. To the other end of the lower feeding roller J, is secured a small spur wheel P, of eight teeth working into another Q, in the top one of the like number of teeth which produces the reverse motion in the top feeding roller R. The lower feeding roller J also, turns a small connecting spur wheel S, which drives another T, each having eight teeth and that one marked T is secured to the end of the feeding table roll N thereby giving it the same motion as the lower J and consequently brings forward the feeding cloth U, which is kept stretched by means of the tightening Roller W, which can be set further off by means of the thumb screw and groove in the piece X at the other end of the frame and behind the beating cylinder B, is placed another cylinder or revolving comb Y consisting of arms through the axis supporting bars along this axis, armed with long teeth there forming combs Z, which teeth are set so as when they begin to descend into their concave bed they assume a horizontal position. The axis of this cylinder or comb carries a pulley of about five inches in diameter (3) on the same side of the frame as the pulley on the beating cylinder, and is driven by said beater pulley and a belt. The bed of this cylinder is composed of bars, H, set at such a distance apart as to let the grain fall through into a kind of hopper beneath. When I sometimes apply a common fan to clear the rice or grain from what chaff may remain, but generally the comb carries all off leaving the grain sufficiently clean. covers are adapted to both cylinders.

Operation. The straw containing the grain is spread upon the feeding table and by the motion communicated from the beating cylinder B to the roller thus near the feeders. The cloth is set revolving over its two rollers and carries the grain and straw forward between the feeding Rollers J & R where it is caught by the teeth of the beater and driven over the concave bed D, which breaking out the grain and throws all over to the bed of bars under the comb Z, here the grain fall through, and the straw is driven to the back over the frame being

separated from the grain. What I claim as my invention in the above described machine and ^{not} heretofore known is first the plan of setting the forward feeding table roller nearer to or farther from the feeding rollers as the length or strength of straw may require according to the arrangements I have set forth of the cornered upright bars and greaves sliding upon the thumb screws. Second the application of the cog wheel gearing according to the plan and proportion set forth for driving the feeding rollers. Third. the application of a beating cylinder with stationary bars and square, or rather oblong teeth (or with the hinge beat-
ing though I do not claim the invention thereof) to a concave bed as described above. Though I do not claim said form of bed as my invention. Fourth. the application of the comb driven as above set forth and over the bed above described, though I do not claim the invention of said comb and bed. The machine above described has been fully tested as to its efficiency and practicability, and has been decidedly approved of as by far the best combination for the planter or grower of rice or any other small grain, that has been hereto-
fore devised for their use whether taking into consideration the ease and cheap-
ness of construction, the facility with which any repairs can be made as above
all the great perfection with which the work is executed. In testimony that
the above is a full clear and exact description of the construction and use
or mode of operation of my machine as invented or improved by me. I have here-
unto set my hand this thirteenth day of July eighteen hundred & thirty five

Witnessed
